

# Colour ringing, population models, and bad Aquatic Warbler years

## Introductory remarks

Jochen Bellebaum & Franziska Tanneberger

# Pomeranian population 1993-2008

# Sedge Warbler survival and AW trends

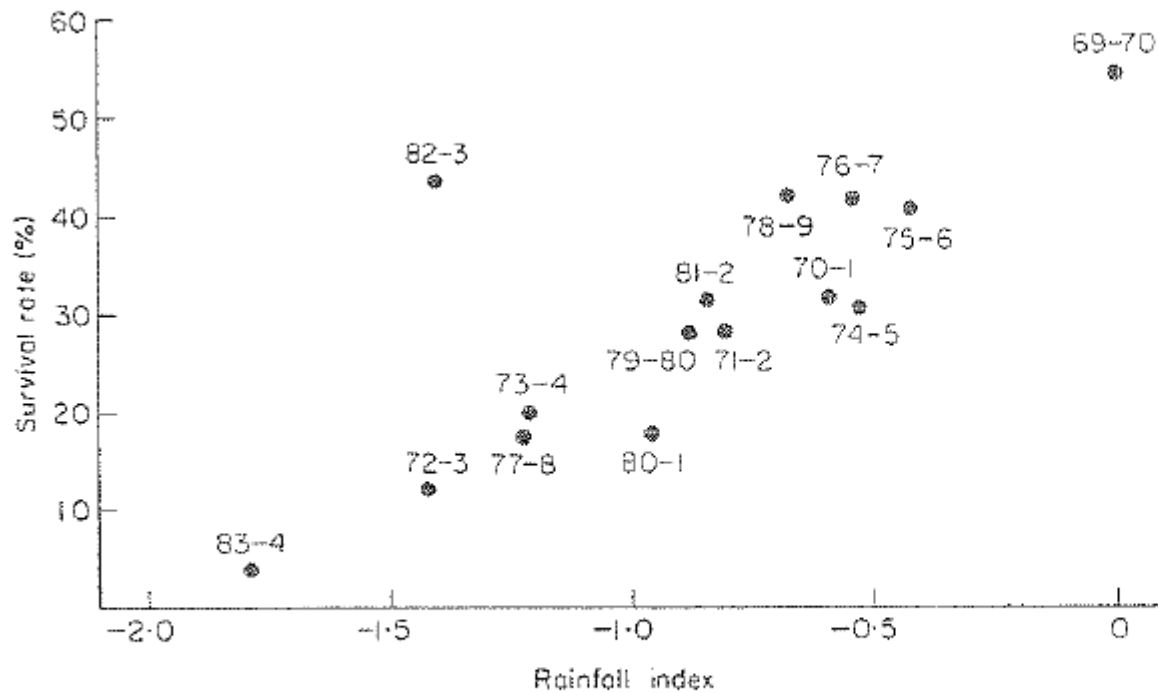

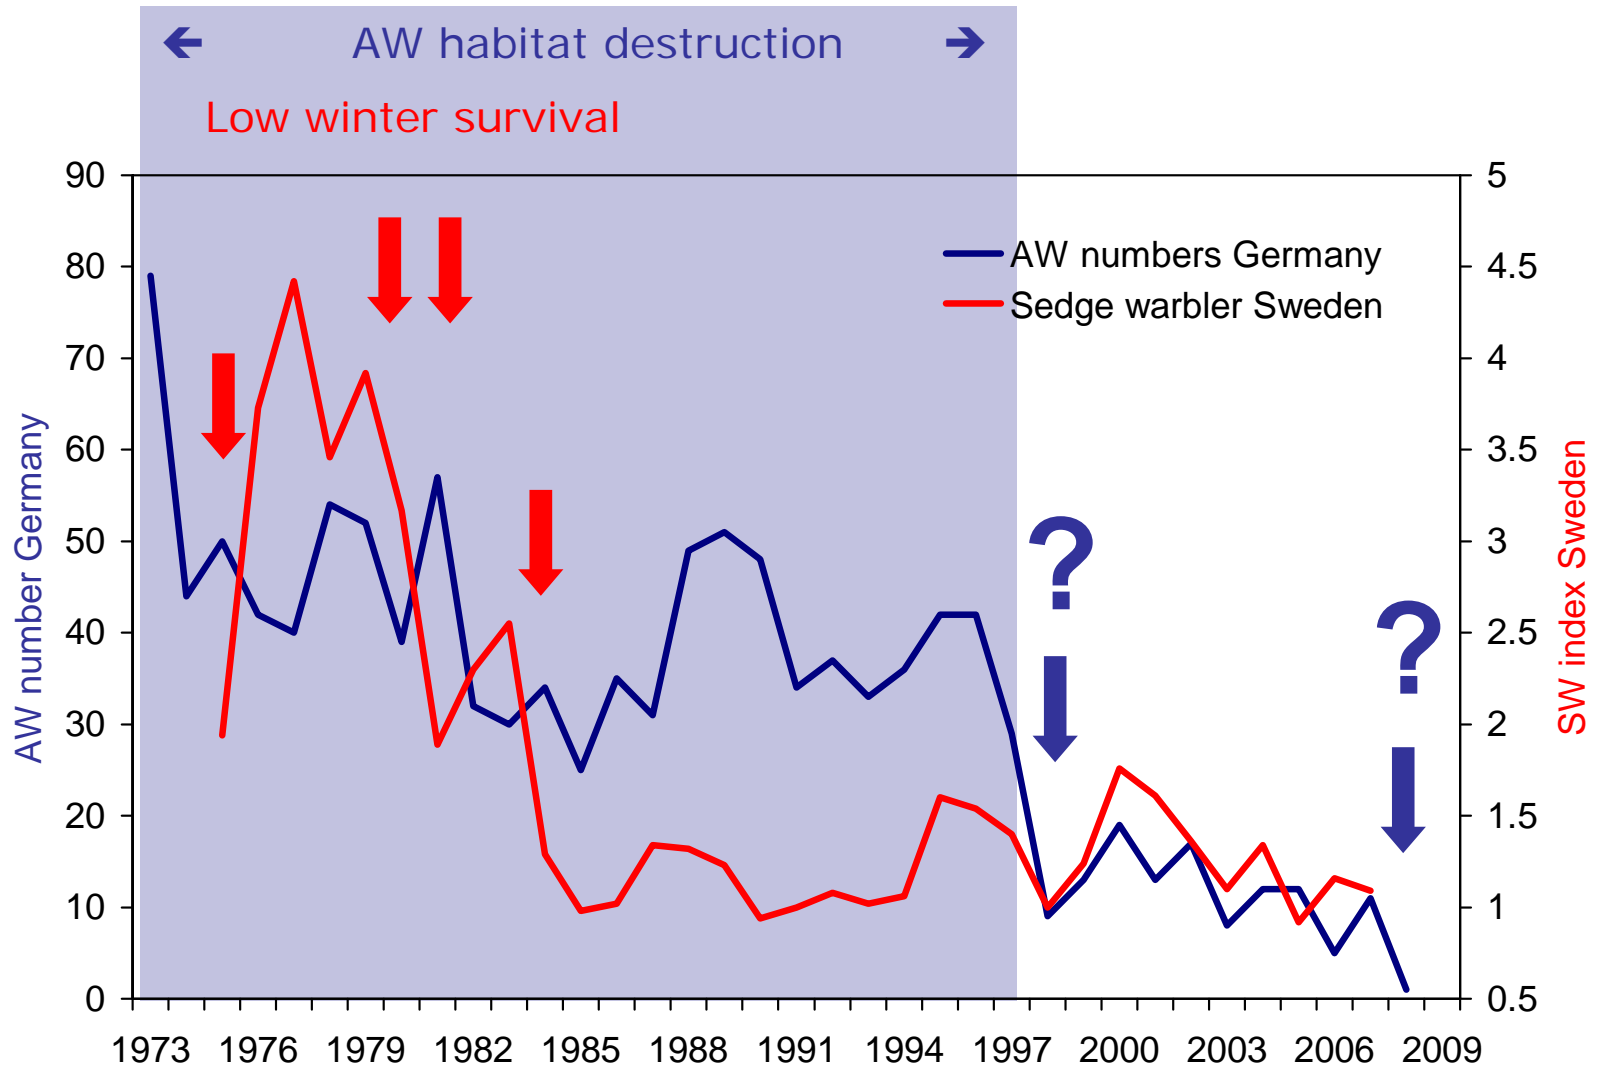

Figure 4. Estimated annual survival rates (%) of adult Sedge Warblers trapped between 1969 and 1984 at two sites in southern England plotted against an index of annual rainfall for the previous wet season (May–October) in the West African winter quarters. Survival estimates were generated by program SURGE (Clobert *et al.* 1987; Pradel *et al.* 1991) in which survival was modelled as time-dependent but site-independent, and recapture probability site-dependent and constant over time (Model (St. Ps) in Table 1).

# Sedge Warbler survival and AW trends

### Habitat

Analysis of habitat selection (habitat modelling)

### Individual

Nest observations, (colour) ringing, genetic analyses

### Population

Trend analysis and general population modelling

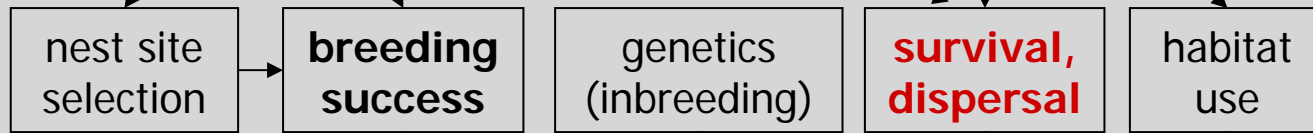

Evaluation of conservation measures and advice to administration/policy

### Habitat

Analysis of habitat selection (habitat modelling)

### Individual

Nest observations, **(colour) ringing**, genetic analyses

### Population

Trend analysis and general population modelling

Evaluation of conservation measures and advice to administration/policy

# Information from (colour) ringing

Exchange rates (Pomerania)

Survival estimation

capture-mark-recapture/resighting analysis

In case of AW most promising:

colour ringing (more resightings)

isolated populations (smaller bias due to emigration)

Further possibilities:

- CMR data from staging areas?
- daily survival estimates in Senegal

# Next steps

- (1) Create ringing and recapture/resighting database
- (2) Intensify current colour ringing/resighting activities where useful
- (3) Analyse CMR data – in particular from breeding areas:
  - historical data (Rietzer See)
  - Biebrza valley (1995-97)
  - Belarus
  - Pomerania (since 1999)
